Word and sentence embeddings

Quiz, 5 questions

1 point

1.

Compute a second-order co-occurrence between the words *'These'* and *'So'* (the cosine similarity between their first-order co-occurrence vectors). Use the toy corpus:

These are the wrong sort of bees. Quite the wrong sort. So I should think they would make the wrong sort of honey.

- Let's define a context of a word as three words to the left and three words to the right from the target word, **occurred within the same sentence** (if there are any).
- Forthe first-order co-occurrence, let's consider pPMI values (the formula was given on slide 5 of the first video).

Hint: in this question you actually do not need to *compute* anything... And the answer would be the same for any type of first-order co-occurrence.

- 1
- 0
- -1
- $\frac{1}{\sqrt{2}}$
- 2

2.

Choose correct statements about Singular Value Decomposition (SVD), an important notion from the linear algebra. Feel free to consult any additional resource like wiki if needed.

- [x] Singular values decomposition is not unique (for example, the zero matrix can be decomposed in infinitely many ways).
- [x] Truncated SVD is the best rank k approximation of the original matrix in terms of Frobenius norm.
- [x] Squares of singular values of a matrix X are eigenvalues of $X^T X$ (or $X X^T$).
- [ ] Singular values of a rectangular matrix are its eigenvalues.
- [ ] Singular values can be negative.
- [x] Any rectangular matrix with real entries has a singular value decomposition.

3.

Find the objective function of the GloVe model.

- [ ] $\sum_{u \in W} \sum_{v \in C} \left(n_{uv} \log \sigma(\langle \phi_u, \theta_v \rangle) + k \, \mathbb{E}_{\tilde{v}} \log \sigma(-\langle \phi_u, \theta_{\tilde{v}} \rangle) \right)$
- [x] $\sum_{u \in W} \sum_{v \in C} f(n_{uv}) \left(\langle \phi_u, \theta_v \rangle + b_u + b'_v - \log n_{uv} \right)^2$
- [ ] $\sum_{u \in W} \sum_{v \in C} n_{uv} \frac{\exp \langle \phi_u, \theta_v \rangle}{\sum_{\tilde{u} \in W} \exp \langle \phi_{\tilde{u}}, \theta_v \rangle}$
- [ ] $\sum_{u \in W} \sum_{v \in C} \left(n_{uv} \langle \phi_u, \theta_v \rangle - k \, \mathbb{E}_{\tilde{v}} \langle \phi_u, \theta_{\tilde{v}} \rangle \right)$

4.

How are word embeddings usually evaluated (qualitatively or quantitively)?

- [ ] By comparing maximal lengths of word vectors (the more is the length, the better is the model).
- [x] By the interpretability of the components of the vectors.
- [x] By the accuracy of analogy prediction (using some pre-defined dataset of 4-word analogies).
- [ ] By the amount of positive components of word vectors.
- [x] By Spearman's correlation (or similar rank correlation measure) with human judgements on word similarity task.

---

5.

Choose the correct statements.

- [ ] Word2vec works fine for word analogies, but there are many concerns with word similarities.
- [ ] Skip-gram negative sampling (SGNS) model is too hard to train, and it is often approximated with softmax.
- [x] For word similarity tasks, count-based methods perform on par with predictive methods.
- [x] Representations of word or character n-grams may improve the quality of the model.
